

Container with Alignable Dispensing Openings

Abstract

A double closure selectively aligns or non-aligns openings in a container such as a dispensing container. An inner lid provides an inner dispensing opening in an inner closure panel. A seal wall depends from the inner closure panel and fits within the open end of a container in a sealing relationship. An outer lid provides an outer dispensing opening in an outer closure panel. A peripheral wall depends from the outer closure panel, fits over the top of the inner closure panel and fits around the outside face of the container body. Engaging devices between the two lids and between the outer lid and the container body maintain the necessary spacing for the lids to seal against each other when the outer lid is twisted to selectively bring the outer dispensing opening out of alignment with the inner dispensing opening.
